CONTROL, COORDINATION AND CONFLICT ON
INTERNATIONAL COMMODITY MARKETS *)

Willem van Groenendaal
Aart de Zeeuw

ABSTRACT

The effects of price stabilisation policies have been investigated for both theoretical and empirical models. The institutional construct for international commodity markets is that a buffer stock manager employs a band width rule or a price adjustment rule to stabilise the world market price. In those investigations it is assumed that the other market participants do not react to the stabilisation activities of the buffer stock manager.

This paper describes an international commodity market as a difference game between buffer stock manager, producing countries and consuming countries and uses an empirical model for the world cocoa market to analyse the effects. The feedback Nash behavioural equilibrium for this game is compared with the optimal control outcome which ignores the strategic behaviour in producing countries and consuming countries. It is found that producers and consumers engage in storage activities which have a negative effect on the stabilisation efforts of the buffer stock manager but which decrease the operating costs of the buffer stock, decrease the revenues of the producers and decrease the costs of the consumers.

Key words: buffer stock price stabilisation, international cocoa market,
optimal control, difference games

Revised July 1989

*) An earlier version of this paper was presented to the Second Economic Modelling Conference, 28-30 March, 1988, London, and to the European Meeting of the Econometric Society, 29 August-2 September, 1988, Bologna. The authors are grateful to the participants of those meetings for their comments and to Jan Potters and Anton Markink for computational assistance.

1. Introduction

International commodity agreements aiming at price and revenue stabilisation are a major policy issue at the meetings of the UNCTAD. Especially during the last conferences the main if not only objective formulated in the agreements is price stabilisation around a long-term trend (see e.g. UNCTAD, 1986). The desirability of price stabilisation has been an important theoretical issue in the economic literature for a long time. Turnovsky (1978) surveys and extends the Waugh-Oi-Massell analysis. Prices are random due to stochastic fluctuations in demand and supply. The criteria for judging the desirability of price stabilisation are the expected producers surplus and the expected consumers surplus. The main conclusion of the Waugh-Oi-Massell-Turnovsky analysis is that the source of the fluctuations determines whether the surplus improves or deteriorates. In general the sum of the surpluses, that is total welfare, improves. Newbery and Stiglitz (1982) argue that the market is in fact competitive and complete, because future and risk markets are redundant. This implies that the market equilibrium is Pareto efficient, so that the optimal stabilising policy is to reproduce the storage decisions of risk neutral competitive speculators with rational price forecasts. Turnovsky (1978) and Newbery and Stiglitz (1982) emphasize that perfect price stability is either not feasible or infinitely costly. It is better to analyse partial adjustment policies or the optimal degree of price stabilisation. In the literature two types of stabilisation policies are distinguished. The first one is a band width rule, which means that the stabilising agency intervenes when the price moves above or below an a priori specified price band. This is the sort of rule that is suggested in the international commodity agreements and that is referred to by Newbery and Stiglitz (1982) as the pragmatic approach. The second one is a price adjustment rule, which means that the stabilising agency is constantly trying to keep the price as close as possible to an a priori specified target price path. This is the sort of rule that also results from an optimal control approach to the stabilisation problem. Lee and Blandford (1980) use empirical models for the world cocoa and copper markets and perform an optimal control analysis for price and revenue stabilisation. They stress the need

to take account of the systematic trend of the price in setting the target price path, because otherwise the attempts to stabilise are doomed to fail. Their conclusion is that it is likely to require substantial market intervention to produce a significant reduction in price instability, although price stability can have a favourable impact on the level and stability of producers revenues. Ghosh, Gilbert and Hughes Hallett (1982) construct a model of the world copper market in which the market clearing identity is replaced with an explicit price formation mechanism. They compare band width rules with optimal control results and conclude that band width rules are no match for optimal stabilisation schemes. Hughes Hallett (1986) explores the problem further. The conclusion is again that significant stabilisation of the copper market is possible but very expensive. However, in contrast with Lee and Blandford (1980) there now is no improvement of the level of producers earnings, although the variability can be reduced substantially. This is in line with the theoretical results that are reported in Turnovsky (1978).

Turnovsky (1978) and Newbery and Stiglitz (1982) raise the question what the impact might be of the actions of the stabilising authority on private speculative storage and whether the actions of private speculators might jeopardise the desired outcome. Lee and Blandford (1980) and Hughes Hallett (1986) also emphasize the assumption in their exercise that the behaviour of market participants is unaffected by buffer stock stabilisation. The Lucas' critique argues that this assumption is not realistic and might lead to the wrong policy advice. This paper therefore suggests to use a difference game approach instead of an optimal control approach. In this way it is possible to study the effects, when producers and consumers can also employ storage activities in reaction to buffer stock activities and, moreover, when the buffer stock manager realises this. It must be stressed that the Lucas' critique is not completely resolved in this way, because other behaviour is kept fixed in the model. The storage behaviour of buffer stock manager, producers and consumers is modelled as an optimal control problem and the strategic interaction is modelled as a game. It is suggested to employ the feedback Nash or subgame perfect equilibrium concept for this difference game. An algorithm which leads to this equilibrium is given by de Zeeuw (1984). In this paper an empirical model for the world cocoa market is used which is based on a model developed in van

Groenendaal and Vingerhoets (1988). This model consists of estimated equations for production and consumption and for several price indices. The optimal stabilisation policy of the buffer stock manager based on an optimal control approach is compared with the Nash equilibrium between buffer stock manager, producing countries and consuming countries. The idea is that a country modelled as a strategic agent represents all strategic activities within that country. In this Nash equilibrium the producing countries aim at higher export prices and the consuming countries aim at lower import prices. In the attempt to stabilise the world market price the buffer stock manager is restricted by the available buffer stock, which can never become negative. In their attempt to get a better export price or import price the countries are restricted in their storage decisions by assumptions about a reasonable size of the stock. The conclusions are that both producing countries and consuming countries engage in storage activities which counteract the stabilising efforts of the buffer stock manager, although this effect is small. The buffer stock can be successful in stabilising world market prices and revenues, but there remains a conflict on the market which calls for further coordination. Interesting is that the operating costs of the buffer stock decrease in the game setting. Furthermore, when producing countries and consuming countries are both active, the producers are worse off whereas the consumers are better off.

This paper is organised as follows. Section 2 presents an empirical model for the world cocoa market. Section 3 gives algorithms for the optimal control solution and the feedback Nash behavioural equilibrium in a linear quadratic framework. In section 4 the price stabilisation problem is formulated as an optimal control problem, when there is no speculation, and as a Nash difference game, when there is speculation. The algorithms given in section 2 are applied to the model presented in section 1. The results for the optimal control formulation and the Nash difference game formulation are compared. Section 5 concludes the paper.

2. Cocoa Model

Cocoa beans are produced in underdeveloped and less developed countries and cocoa products are mainly consumed in developed countries. This implies that the trade between producers and consumers typically is international trade between countries or regions. The structure of the model reflects this observation. The exports and imports of intermediary cocoa products are transformed into cocoabean equivalents, so that cocoabeans are in fact the only traded goods. Suan Tan (1984, pp. 71-83) reviews the theory underlying the construction of this type of models. The sampling period is in principle 1960-1982 and most data originate from FAO Cocoa Statistics, Gill & Duffus Market Reports and the ICCO Quarterly Bulletin (the attached list of symbols contains a complete description of the data sources).

The producing countries or regions are Cameroon, Ghana, Nigeria, Ivory Coast, Africa Rest, Brazil, Rest South America and Asia and Oceania. The production of cocoabeans depends on the area planted and the average production per acre of land. Akiyama and Duncan (1982) therefore use equations for acreage and for average production in their model. However, since the data for acreage are not reliable (FAO, 1984), here only one equation for production is used. Under fairly reasonable assumptions this is anyway not a severe restriction (Ady, 1968; Bateman, 1965). The decision on a change in production is based on the development (or adaptive expectation) of real producer prices PFI/PC as an indicator of expected profits. The resulting specification is

$$(2.1) \quad \Delta QR_t = \beta_0 + \sum_{j=0}^8 \beta_{j+1} (PFI/PC)_{t-j} + \beta_{10} QR_{t-1}.$$

Table 1 gives the estimation results.

The consuming regions are North America, Western Europe, Eastern Europe (including the USSR) and Rest of developed World. Especially between North America and Brazil there is a large trade in intermediary cocoa products. Therefore the imports consist of cocoabeans for grindings as well as powder, paste and butter transformed into cocoabean equivalents. Cocoa consumption per capita CC/POP is based on real gross per capita income GNPR/POP and on real cocoa prices. The real import price PI/PC is used to

represent the real cocoa price. The real price of sugar PS/PC is introduced to account for possible substitution or complementary products. The resulting specification is

$$(2.2) \quad (CC/POP)_t = \omega_0 + \omega_1(GNPR/POP)_t + \omega_2(PI/PC)_t + \omega_3(PS/PC)_t \\ + \omega_4(CC/POP)_{t-1}.$$

Table 2 gives the estimation results.

The producer prices PFI are expressed in home-currency and the export prices PE in US-dollars. Due to government policy and quality differences these prices are not only related through the exchange rates RE. For the same reason export prices PE and import prices PI are not equal to the world market price PICCO. For all these price equations an autoregressive distributed lag model of the first order was introduced. The resulting specifications are

$$(2.3) \quad PFI_t = \kappa_1 PE_t \times RE_t + \kappa_2 PE_{t-1} \times RE_{t-1} + \kappa_3 PFI_{t-1}$$

$$(2.4) \quad PE_t = \kappa_1 PICCO_t + \kappa_2 PICCO_{t-1} + \kappa_3 PE_{t-1}$$

$$(2.5) \quad PI_t = \kappa_1 PICCO_t + \kappa_2 PICCO_{t-1} + \kappa_3 PE_{t-1}.$$

Tables 3, 4 and 5 give the estimation results.

The world market cocoa price PICCO depends on the difference between world supply and demand. Buffer stock operations ΔBST have a direct influence on this difference. Supply ERWT sums up the production per country or region minus a change ΔST in stocks, which is held for strategic reasons in that country or region. Demand IRWT sums up the demand for grindings per region plus the imports of cocoabean equivalents plus a strategically held change ΔST in stocks. Apart from stocks held for strategic reasons it is also assumed that the consuming regions keep a fraction of the demand for grindings in stock for production of cocoa products. This desired level of stocks is set equal to the average level of stocks over the period 1968-1980 ($.225 \times IRWT$). The definitional equation for total demand IRWT also includes an autonomous component CCRR to account for imports in countries

or regions, which are not modelled explicitly. Differences in world supply and demand will also create changes $\Delta STWT$ in free stocks of cocoabean equivalents (the factor .99 accounts for transportation losses). These free stocks will influence the world market price in as far as they differ from the desired level of stocks. Changing demand will induce a change in the desired level of stocks ($.225 \times \Delta IRWT$). This will lead to a change in the demand for stocks and therefore this term is added to demand $IRWT$ in the specification for the world market cocoa price. Since markets are not independent the commodity price index CPI is included in the specification in order to separate the effect of differences in supply and demand on the cocoa market from the spill-over effects from other markets. Indicators for the instability of monetary variables did not have any significant influence. The relevant definitional equations and the resulting specification for the world market cocoa price are

$$(2.6) \quad ERWT_t = \sum_{j=1}^8 [QR_{tj} - \Delta ST_{tj}] \quad (\text{World Supply})$$

$$(2.7) \quad IRWT_t = \sum_{i=1}^4 [CC_{ti} + \Delta ST_{ti}] + CCRR_t \quad (\text{World Demand})$$

$$(2.8) \quad STWT_t = STWT_{t-1} + [.99 \times ERWT_t - IRWT_t - \Delta BST] \quad (\text{World Stocks})$$

$$(2.9) \quad PICCO_t = \alpha_1 CPI_t - \alpha_2 [ERWT_t - (IRWT_t + .225 \times \Delta IRWT_t) - \Delta BST_t] \\ - \alpha_3 [STWT_{t-1} - .225 \times IRWT_{t-1}] + \alpha_4 PICCO_{t-1}.$$

Table 6 gives the estimation result.

The global structure of the model is as follows. The non-controllable exogenous variables are the commodity price indices PC for each country or region, real income $GNPR$ and population size POP for each consuming region, an autonomous import component $CCRR$, the general commodity price index CPI , the price index for sugar PS and the exchange rates RE . The instrumental variables are the change ΔBST in the buffer stock and the changes ΔST in stocks for each country or region. These instrumental variables were set equal to zero in the estimation procedures. The endogenous variables are production QR , the producer price index PFI and the export price index PE for each producing country or region, consumption CC and

the import price index PI for each consuming region, total exports ERWT, total imports IRWT, free stocks STWT and the world market price index PICCO. Given time paths for the non-controllable exogenous variables and for the instrumental variables the model generates time paths for the endogenous variables from an appropriate set of initial values. The model is linear in the endogenous and instrumental variables. Non-linearities such as the transformation from nominal to real variables or from US-dollars to home-currency are reflected in the time-varying coefficients of an essentially linear model.

In order to be able to apply control algorithms the model is rewritten in state-space form. This means that the set of higher-order difference equations is rewritten as a set of first-order difference equations by stacking lagged endogenous and instrumental variables into a state vector and by solving this set of equations for the state transition. The result is

$$(2.10) \quad x_{t+1} = A_t x_t + \sum_{i=1}^{13} B_t^i u_t^i + z_t,$$

where x is the state vector and u^i the instrumental vector for market participant i , $i=1, \dots, 13$, and where the exogenous influences are reflected in the time-varying parameters A , B and z . The state vector consists of all the endogenous variables with one lag and the producer price indices PFI up to their maximum lag, which adds up to 75 elements. The instrumental vectors have only one element. The objective variable of the buffer stock manager is the world market price. In the game exercises in sections 3 and 4 the producing countries or regions have as objective variable their export price index and the consuming regions their import price index. Since these objective variables form a subset of the state variables the vector y of objective variables can be written as

$$(2.11) \quad y = Cx.$$

In section 3 control and game algorithms are given for the abstract model (2.10)-(2.11). In section 4 these algorithms are applied to the underlying world cocoa model (2.1)-(2.9).

3. Difference Game Methodology

The objective of the buffer stock manager is to keep the world market price as close as possible to an a priori specified target price path by selling and buying on the world market. Therefore the basic part of the objective functional of the buffer stock manager consists of squared deviations of the world market price path $PICCO$ from this target price path $\underline{PICCO}$. The interventions of the buffer stock manager are restricted by the available buffer stock and/or the available budget. An optimal degree of price stabilisation can be found by using as objective functional the weighted sum of squares over a fixed planning horizon

$$(3.1) \quad \sum_{t=1}^T [q(PICCO_t - \underline{PICCO}_t)^2 + r(\Delta BST_t)^2].$$

A high value for the relative priority q/r will generally lead to a good stabilisation result with strong interventions, whereas a low value for q/r will generally lead to a bad stabilisation result with minor interventions. Given the restrictions on interventions there will generally be a best stabilisation result corresponding with an optimal value for the relative priority q/r .

The objective functionals of the other market participants are formulated in the same way with the world market price replaced by the export price for the producing countries or regions and by the import price for the consuming regions. These objective functionals reflect the idea that, although producing and consuming countries and regions participate in the buffer stock in order to stabilise prices, there may be additional storage activities in these countries and regions in order to try to get higher export prices or lower import prices. This leads to a strategic interaction between buffer stock manager, producers and consumers, which can be modelled as a difference game. In terms of the state-space form (2.10)-(2.11) of the model this difference game consists of the objective functionals

$$(3.2) \quad J_i(u^1, \dots, u^{13}) := \sum_{t=1}^T [(y_t - \hat{y}_t^i)' Q_t^i (y_t - \hat{y}_t^i) + u_t^{i'} R_t^i u_t^i], \quad i=1, \dots, 13,$$

and the constraints (2.10)-(2.11), where y^i are the vectors of target price paths and where the diagonal matrices Q^i are semi-positive definite and the scalars R^i are positive. The quadratic form of the objective functionals implies that deviations above and below the target paths are equally punished. This is a suitable type of criterium for stabilisation purposes. However, in this game it is not the objective of producers and consumers to stabilise prices, but to get higher export prices or lower import prices. A way out is to set the target path of export (import) prices high (low) enough so that the resulting price path remains below (above) the target price path. The precise choice of the target paths as well as the relative priorities q/r must again be motivated by the desirability and the feasibility of the outcomes (see also section 4).

Suppose the buffer stock manager is labelled as player 1, the producing countries or regions are labelled as players 2,...,9 and the consuming regions are labelled as players 10,...,13. In case $Q^i=0$, $i=2,...,13$, the producing and consuming countries and regions do not act and there remains an optimal control problem for the buffer stock manager.

The behavioural equilibrium concept used to solve the difference game is the noncooperative Nash concept. It is important to distinguish between the Nash solution with only initial state information and with binding commitments and the Nash solution with current state information and without binding commitments (Başar and Olsder, 1982; de Zeeuw and van der Ploeg, 1987). The first one is called the open-loop Nash solution and the second one is called the feedback Nash or subgame-perfect solution. Since it seems more realistic to assume the use of current state information and no binding commitments, the feedback Nash solution is employed here. This behavioural equilibrium is found by solving static Nash games in a dynamic programming framework. The equilibrium strategies are given by (de Zeeuw, 1984)

$$(3.3) \quad u_t^i(x) := G_t^i x + h_t^i, \quad i=1, \dots, 13,$$

where

$$(3.4) \quad G_t^i := -[R_t^i]^{-1} B_t^{i'} K_{t+1}^i [E_{t+1}]^{-1} A_t$$

$$(3.5) \quad h_t^i := -[R_t^i]^{-1} B_t^{i'} \{K_{t+1}^i [E_{t+1}]^{-1} (z_t - \sum_{j=1}^{13} B_t^j [R_t^j]^{-1} B_t^{j'} g_{t+1}^j) + g_{t+1}^i\}$$

$$(3.6) \quad E_{t+1} := I + \sum_{j=1}^{13} B_t^j [R_t^j]^{-1} B_t^{j'} K_{t+1}^j$$

and where K^i satisfy the coupled backward recursive Riccati-type matrix equations

$$(3.7) \quad \begin{aligned} K_t^i &= C' Q_t^i C + A_t' [E_{t+1}]^{-1} (I + K_{t+1}^i B_t^i [R_t^i]^{-1} B_t^{i'}) K_{t+1}^i [E_{t+1}]^{-1} A_t, \\ K_{T+1}^i &= 0 \end{aligned}$$

and g^i satisfy the coupled backward recursive tracking equations

$$(3.8) \quad \begin{aligned} g_t^i &= -C' Q_t^i \hat{y}_t^i + A_t' [E_{t+1}]^{-1} (I + K_{t+1}^i B_t^i [R_t^i]^{-1} B_t^{i'}) \\ &\quad \{K_{t+1}^i [E_{t+1}]^{-1} (z_t - \sum_{j=1}^{13} B_t^j [R_t^j]^{-1} B_t^{j'} g_{t+1}^j) + g_{t+1}^i\} \\ g_{T+1}^i &= 0. \end{aligned}$$

The variable x in the strategy representations (3.3) denotes the state information at time t . In a simulation it is assumed that the players observe the simulated state vector.

4. Cocoa Market as a Game

In this section two strategic interventions on the international cocoa market are compared. In the first one a buffer stock manager tries to stabilise the world market price by selling and buying on the world market from an available buffer stock. In the second one producers and consumers take account of these buffer stock activities and consider to intervene for themselves aiming at higher export prices or lower import prices. The buffer stock manager realizes this, so that the three market participants play a Nash game between them. In the first exercise the buffer stock manager employs the optimal control strategy u^1 given by equations (3.3)-(3.8) with $Q^i=0$, $i=2, \dots, 13$. In the second exercise the players employ the

set of Nash strategies u^i , $i=1,\dots,13$, also given by equations (3.3)-(3.8). Both control and Nash game algorithms start from the model parameters (A_t, B_t, z_t) , the initial state vector x_1 , the target paths $\hat{y}^i$ and the relative priorities (Q^i, R^i) .

The target path for the world market price should reflect the idea that the buffer stock manager only tries to counter undesirable market forces on the international cocoa market and not the spill-over effects from other markets. Therefore this target path is constructed as follows (see for other ideas for the construction of target price paths Lee and Blandford, 1980; Ghosh, Gilbert and Hughes Hallett, 1982; Hughes Hallett, 1986). Firstly, the world market price PICCO is simulated with the cocoa model from section 2 and a trend is determined. Secondly, the world market price PICCO is simulated with equation (2.9) in which α_2 and α_3 are set equal to zero, which implies market equilibrium, and again a trend is determined. Finally, the deviations from trend in the second simulation are added to the trend found in the first simulation. The resulting price path is taken as target path for the world market cocoa price. It seems logical to use this target path and equations (2.4) and (2.5) to construct target paths for the export and import prices. However, this would typically lead to additional stabilisation efforts and not to the sort of conflict that is supposed to be analysed here. In that conflict producers and consumers are trying to get higher export prices and lower import prices, respectively, and not stable prices. They aim at a better result than what they would get when they do nothing. Therefore, the construction of these target paths is based on the resulting price paths from the control experiment. The target paths for export prices are set 10% higher than what comes out of the control experiment and the target paths for import prices are set 10% lower.

The control experiment is set up as follows. The buffer stock manager is given an initial buffer stock of 100,000 mt. The relative priority Q_{11}^1/R^1 is determined by experiment. The value of R^1 is arbitrarily set at 10. Starting at 0 the value of Q_{11}^1 is gradually increased until the accumulated buffer stock changes just hit the ceiling of 100,000 mt somewhere in the sampling period, which happens for $Q_{11}^1=30$. This is the best stabilisation result the buffer stock manager can achieve with the available buffer stock. The results are presented in table 7.

The game experiment is essentially set up in the same way. The values of R^i , $i=2, \dots, 13$, are also arbitrarily set at 10. The values of Q_{ii}^i , $i=2, \dots, 13$, are also gradually increased starting at 0 until the accumulated interventions on the producers' side and the consumers' side unrealistically exceed a preset value of about 140,000 mt. From the experiments it is found that an increasing Q_{ii}^i , which must lead to higher export prices and lower import prices, respectively, also leads to more income for the producing countries and regions and less costs for the consuming regions. This implies that prices are a good indicator for revenues and costs, so that the experiment was set up realistically in that respect in the first place. It remains to be seen what happens when both producers and consumers try to improve their situation by speculative actions.

The results of the game experiment are presented in three steps. Firstly, there is only a game between buffer stock manager and producing countries and regions in which the consuming regions remain passive. This game is called game 1. Secondly, there is only a game between buffer stock manager and consuming regions in which the producing countries and regions remain passive. This game is called game 2. Finally, the game between the three market participants is called game 3. It is found that in the games with consuming regions there is some more room for the buffer stock manager to operate. In these games the value of Q_{11}^1 can be increased to 35. In game 1 the preset boundary for the producing countries and regions is hit for $Q_{ii}^i=6$, $i=2, \dots, 9$. In game 2 the preset boundary for the consuming regions is hit for $Q_{ii}^i=10$, $i=10, \dots, 13$. In game 3 the preset boundaries are hit for $Q_{ii}^i=5$, $i=2, \dots, 9$, and $Q_{ii}^i=9$, $i=10, \dots, 13$. It is possible to vary the values of Q_{ii}^i over the different countries and regions and over time. An idea is to relate these values to the size of the trade of each country and region, so that the resulting interventions will also be related to the size of the trade. It proves that the market results remain essentially the same. The reason is that the interventions of the producers as a group and of the consumers as a group remain essentially the same. The results with these values for Q_{ii}^i are presented in table 8 for game 1, table 9 for game 2 and table 10 for game 3.

The first conclusion from the figures in tables 7-10 is that the pattern of the buffer stock interventions is the same in all four experiments. The buffer stock manager starts to sell for three periods, then buys for three

periods, then sells again for four or five periods and ends up buying. In total the buffer stock manager is a seller. The producing countries or regions are predominantly withholding to lower supply in order to increase prices and the consuming regions are predominantly using up their stocks to lower demand in order to decrease prices, which is to be expected.

As an indicator for the degree of stabilisation the sum of absolute differences between the values of the resulting price path and the corresponding values of the target price path is used. The optimal control solution leads to a good stabilisation result. This result is somewhat better than for the game solutions. However, the stabilisation indices for the games with consumers are almost as good as for the optimal control solution, whereas the stabilisation index for the game with only producers is quite a bit worse. This means that the destabilising effect is mainly due to the storage activities in the producing countries and regions.

The net sales from the buffer stock are the lowest in the game with only consumers and the highest in the game with only producers. However, this does not mean that the buffer stock manager is less active in game 2. On the contrary, the sum of interventions in absolute terms is the highest in game 2 and the lowest in game 1. What it does imply is that there will be less costs to replenish the buffer stock up to the initial level of 100,000 mt. These costs are calculated by multiplying the required quantity with a simulated world market price. In this simulation it is assumed that every market participant has to restore its initial endowment, which determines fictitious supply and demand, and that there are enough buyers or sellers.

In order to get an indicator for the costs of operating the buffer stock the net inward cash flow into the buffer stock has to be subtracted from these replenishment costs. The costs of operating the buffer stock are the lowest for the game with only producers (game 1). The interventions of the producers induce an upward pressure on the world market price, which leads to a very high net inward cash flow into the buffer stock. These revenues outweigh the high replenishment costs for this game. The costs of operating the buffer stock are also very low for the game with producers and consumers (game 3). The interventions of the producers and consumers almost cancel out, so that the world market price path changes only slightly as compared to the price path in the optimal control solution. Therefore

the net inward cash flow into the buffer stock is almost the same. However, the replenishment costs are much lower. The costs of operating the buffer stock for the game with only consumers (game 2) are higher than for the other two games but still lower than for the optimal control solution. The interventions of the consumers induce a downward pressure on the world market price, which leads to a low net inward cash flow into the buffer stock. However, the replenishment costs are much lower, since there remains a large buffer stock at the end, and this outweighs the lower revenues.

The results of game 1 and game 2 show that the producers and consumers actually benefit from their actions. The pursuit of higher export prices and lower import prices leads to higher revenues and lower costs, respectively. The group that remains passive has a loss. The differences between the gains of the one group and the losses of the other are due to the way in which the market is modelled, when the market participants restore their initial endowments. The differences are a gain or a loss of fictitious traders. The results of game 3 show that when producers and consumers are both active the producers are worse off than in the optimal control solution. The reason is that the attempts of both groups to improve their situation approximately cancel out, so that withholding and dumping implies a loss. On the other hand, the consumers are better off, because they restore their used stocks at a favourable price. The values are, however, rather small.

These budget considerations are important to put the results with respect to the stabilisation issue in the right perspective. Although the general conclusion is that the buffer stock stabilisation activities are less successful when producing and consuming countries and regions also employ storage activities for their own sake, this conclusion is weakened by the fact that the operating costs of the buffer stock are much lower. Furthermore, the producers have lower revenues and the consumers have lower costs. A topic of further research will be to make an overall cost and benefit analysis and to see if the results are robust for reasonable variations in the target paths and the relative priorities. Finally, the issue of coordination through the buffer stock and conflict on the market afterwards could be analysed further with other noncooperative and cooperative game theoretic solution concepts.

5. Conclusion

This paper tries to answer the question what happens if agents in producing and consuming countries are still strategically active on the international cocoa market, although the countries coordinate their stabilising efforts through a buffer stock manager. An empirical model for the world cocoa market is constructed and the optimal control solution for the buffer stock manager is compared with feedback Nash or subgame-perfect game equilibria between buffer stock manager, producers and consumers. The conclusion is that the stabilising efforts are partly offset by the strategic activities of the other market participants. However, the costs of operating the buffer stock decrease and some other market participants are better off. A further treatment of the trade-off between the stabilisation result, on the one hand, and costs and revenues, on the other hand, and the study of other game equilibria are left for further research.

*) The following restrictions were introduced: $\beta_1 = \beta_2$, and $\beta_9 = \beta_6 + \beta_7 + \beta_8$.

Remark: In addition to the variables of section 2, three other factors were introduced. Firstly, a dummy variable DU65 for the year 1965, in which year the weather conditions were extremely good. Secondly, a variable HY which represents a change in technology due to the introduction of hybrids. Thirdly, a time trend t for Asia and Oceania, which reflects the policy of increasing the acreage for cocoatrees by the local governments.

Table 2: Consumption

$CC/POP_t = \omega_0 + \omega_1(GNPR/POP)_t + \omega_2(PI/PC)_t + \omega_3(PS/PC)_t + \omega_4(CC/POP)_{t-1}$				
country or region	NA	WE	EE	RW
ω_0 t^0	. ()	.70 (4.3)	. ()	.30 (2.9)
ω_1 t^1	.10 (2.6)	.06 (2.6)	2.48 (4.3)	.08 (2.8)
ω_2 t^2	-.17 (-2.9)	-.08 (-3.2)	-.38 (-4.3)	-.11 (-2.8)
ω_3 t^3	-.35 (-2.55)	-.13 (-1.8)	. ()	. ()
ω_4 t^4	.78 (7.1)	.49 (3.9)	.30 (1.6)	.51 (3.1)
R^2	.78	.77	.78	.82

Remark: For Eastern Europe and the USSR there are no figures on the price of consumption. Therefore PI and PS were used instead of the relative prices.

Table 3: Producer prices

$PFI_t = \kappa_1 PE_t \times RE_t + \kappa_2 PE_{t-1} \times RE_{t-1} + \kappa_3 PFI_{t-1}$								
country or region	CA	GH	NI	IC	AR	BR	RA	AO
κ_1 t^1	.05 (1.8)	.18 (5.7)	. .	.07 (1.1)	.12 (2.6)	.74 (20.3)	. .	. .
κ_2 t^2	.15 (3.6)	. .	.21 (2.6)	.16 (2.2)	.10 (1.2)	-.45 (-2.4)	. .	. .
κ_3 t^3	.63 (7.7)	.63 (6.6)	.79 (5.1)	.59 (4.4)	.65 (4.0)	.60 (2.1)	. .	. .
R^2	.99	.98	.98	.97	.98	.99		

Remark: For the Rest of South America (RA) and Asia and Oceania (AO) producer prices are not known. It is assumed that for these regions producer prices are equal to export prices in home-currency: $PFI = PE \times ER$. For the rest of Africa an index (1975 = 100) was used based on the sum of producer prices in US-dollars, weighted with the production.

Table 6: The world market cocoa price

$PICCO_t = \alpha_1 CPI_t - \alpha_2 [ERWT_t - (IRWT_t + .225 \times \Delta IRWT_t)]$ $- \alpha_3 [STWT_{t-1} - .225 \times IRWT_{t-1}] + \alpha_4 PICCO_{t-1} + \alpha_5 DU77$

1979	20.46	271.60	297.11	289.30
1980	28.66	225.00	297.46	246.50

$$\sum_{t=68}^{80} = -52.29$$

$$\min_t \{BST_t\} = BST_{77} = -6.17$$

operating costs : 59,073,000.- US-dollars

inward cash flow : 75,728,000.- US-dollars

stabilisation index (simulation) : 341.59

stabilisation index (control) : 228.62

Remark: The stabilisation index is defined as $\sum_{t=68}^{80} |PICCO - \underline{PICCO}|$. The operating costs for the buffer stock manager are defined as

$$\sum_{t=68}^{80} \Delta BST_t \times PICCO_t + (BST_{67} - BST_{80})(PICCO_{80} - [-.216 \times (BST_{67} - BST_{80})]).$$

The first term is the total yearly outward cash flow from selling and buying. The second term represents the costs for restoring the buffer stock at its initial level. The warehouse costs of the buffer stock are not taken into account.

List of symbols

- BST Buffer stock in 1000mt.
- CC Consumption of cocoa in 1000 mt.
Calculated by adding grindings and imports in bean equivalents of the various consuming areas. CCRR is obtained by subtracting the consumption in the other four areas from world grindings.
FAO Cocoa Statistics (1951-1973) and Gill & Duffus Market Report (1974-1985)
- CPI Commodity price index (1980 = 100).
International Financial Statistics, 1953-1985
- ERWT World supply of cocoa beans: $\sum_{j=1}^8 QR_j - \Delta ST_j$.
- IRWT World demand for cocoa beans: $\sum_{j=1}^4 CC_j - \Delta ST_j$.
- GNPR Gross national product in purchasers values in billions of US-dollars (at exchange rates and prices levels of 1975).
Data available for the period 1960-1982 for Western Europe and North America. For the the rest of the developed world we used the data from Japan, Australia and New Zealand. The source is OECD National Accounts. For Eastern Europe and the USSR the data are taken from the Year-book of National Accounts (available as an index (1975 = 100) for the period 1960-1980).
OECD National Accounts and Yearbook of National Accounts.
- HY Percentage of total area planted with cocoa that is planted with hybrid varieties. This is defined only for Ivory Coast and Brazil.
'World Cocoa Production, Consumption and Price Prospectives' by M.J. Bateman, Mimeo. Period 1966-1983.
- PC Index of consumption prices (1975 = 100).
For the consuming regions this index is calculated by dividing nominal private consumption per region by real private consumption per region at 1975 prices and exchange rates from the OECD National Accounts for the period 1960-1982. For Eastern Europe and the USSR no data are available. For the producing countries data are available per country for the period 1953-1984 (except for Cameroon and Ivory Coast) from the International Financial Statistics. For Cameroon and Ivory Coast data for the missing years (1953-1962 and 1953-1960 respectively) were constructed by regressing the index for each country on the index for total Africa and 'predict' the missing observations. For the three remaining areas data are constructed as follows:
Africa Rest, the consumer index for total Africa, period 1953-1984.
Asia and Oceania, the consumer price index for total Asia, period 1953-1984.
Rest America, the average of the consumer price indices (weighted with production of beans) of Ecuador, Mexico and the Dominican Republic, period 1956-1984.
OECD National Accounts and International Financial Statistics.

- PE Unit value of exports in US-dollarcents per kilo.
Nominal exports are divided by real exports in 1975 prices.
FAO Cocoa Statistics and FAO Trade Yearbook, 1956-1982.
- PFI Index of producer prices in home-currency (1975 = 100).
Producer prices in home-currency are available for countries. For Africa Rest a weighted average of producer prices in US dollar cents of the four other countries is used. Producer prices for the Rest of South America and Asia and Oceania are set equal to export prices. Data are available for: Cameroon (1958-1982), Ghana (1953-1982), Ivory Coast (1957-1982), Nigeria (1953-1982), Brazil (1966-1982).
Gill & Duffus Market Report.
- PI Unit value of imports in US-dollarcents per kilo.
Nominal imports are divided by real imports in 1975 prices.
FAO Cocoa Statistics and FAO Trade Yearbook, 1955-1982 (except for Eastern Europe and the USSR, 1965-1982).
- PICCO Annual average of daily prices of cocoabeans in US-dollarcents per kilo.
FAO Cocoa Statistics and Quaterly Bulletin of Cocoa Statistics, 1960-1985.
- POP Population in millions.
OECD National Accounts and Yearbook of National Accounts, 1960-1982.
- PS Price of sugar on the world market in US-dollarcents per kilo.
Trends & Prices, 1960-1982.
- QR Production of cocoabeans in 1000 mt per annum (1 oct. - 30 sept.).
FAO Cocoa Statistics and ICCO Quarterly Bulletin of Cocoa Statistics, 1951-1985.
- RE Rate of exchange in units per US-dollar (for regions RE equals 1).
International Financial Statistics, 1953-1985.
- ST Strategic stocks held by a producing and consuming countries.
- STWT Free world stocks of cocoabeans in 1000 mt.
Calculated starting from 1960 stocks as reported by Gill & Duffus.

Determinanten van de vraag naar vakantiereizen: een verkenning van
materiële en immateriële factoren
- 311 Peter M. Kort
Dynamic Firm Behaviour within an Uncertain Environment
- 312 J.P.C. Blanc
A numerical approach to cyclic-service queueing models

- 313 Drs. N.J. de Beer, Drs. A.M. van Nunen, Drs. M.O. Nijkamp
Does Morkmon Matter?
- 314 Th. van de Klundert
Wage differentials and employment in a two-sector model with a dual labour market
- 315 Aart de Zeeuw, Fons Groot, Cees Withagen
On Credible Optimal Tax Rate Policies
- 316 Christian B. Mulder
Wage moderating effects of corporatism
Decentralized versus centralized wage setting in a union, firm, government context
- 317 Jörg Glombowski, Michael Krüger
A short-period Goodwin growth cycle
- 318 Theo Nijman, Marno Verbeek, Arthur van Soest
The optimal design of rotating panels in a simple analysis of variance model
- 319 Drs. S.V. Hannema, Drs. P.A.M. Versteijne
De toepassing en toekomst van public private partnership's bij de grote en middelgrote Nederlandse gemeenten
- 320 Th. van de Klundert
Wage Rigidity, Capital Accumulation and Unemployment in a Small Open Economy
- 321 M.H.C. Paardekooper
An upper and a lower bound for the distance of a manifold to a nearby point
- 322 Th. ten Raai, F. van der Ploeg
A statistical approach to the problem of negatives in input-output analysis
- 323 P. Kooreman
Household Labor Force Participation as a Cooperative Game; an Empirical Model
- 324 A.B.T.M. van Schaik
Persistent Unemployment and Long Run Growth
- 325 Dr. F.W.M. Boekema, Drs. L.A.G. Oerlemans
De lokale produktiestructuur doorgelicht.
Bedrijfstakverkenningen ten behoeve van regionaal-economisch onderzoek
- 326 J.P.C. Kleijnen, J. Kriens, M.C.H.M. Lafleur, J.H.F. Pardoel
Sampling for quality inspection and correction: AOQL performance criteria

- 327 Theo E. Nijman, Mark F.J. Steel
Exclusion restrictions in instrumental variables equations
- 328 B.B. van der Genugten
Estimation in linear regression under the presence of heteroskedasticity of a completely unknown form
- 329 Raymond H.J.M. Gradus
The employment policy of government: to create jobs or to let them create?
- 330 Hans Kremers, Dolf Talman
Solving the nonlinear complementarity problem with lower and upper bounds
- 331 Antoon van den Elzen
Interpretation and generalization of the Lemke-Howson algorithm
- 332 Jack P.C. Kleijnen
Analyzing simulation experiments with common random numbers, part II: Rao's approach
- 333 Jacek Osiewalski
Posterior and Predictive Densities for Nonlinear Regression. A Partly Linear Model Case
- 334 A.H. van den Elzen, A.J.J. Talman
A procedure for finding Nash equilibria in bi-matrix games
- 335 Arthur van Soest
Minimum wage rates and unemployment in The Netherlands
- 336 Arthur van Soest, Peter Kooreman, Arie Kapteyn
Coherent specification of demand systems with corner solutions and endogenous regimes
- 337 Dr. F.W.M. Boekema, Drs. L.A.G. Oerlemans
De lokale produktiestructuur doorgelicht II. Bedrijfstakverkenningen ten behoeve van regionaal-economisch onderzoek. De zeescheepsnieuwbouwindustrie
- 338 Gerard J. van den Berg
Search behaviour, transitions to nonparticipation and the duration of unemployment
- 339 W.J.H. Groenendaal and J.W.A. Vingerhoets
The new cocoa-agreement analysed
- 340 Drs. F.G. van den Heuvel, Drs. M.P.H. de Vor
Kwantificering van ombuigen en bezuinigen op collectieve uitgaven 1977-1990
- 341 Pieter J.F.G. Meulendijks
An exercise in welfare economics (III)

- 342 W.J. Selen and R.M. Heuts
A modified priority index for Günther's lot-sizing heuristic under capacitated single stage production
- 343 Linda J. Mittermaier, Willem J. Selen, Jeri B. Waggoner, Wallace R. Wood
Accounting estimates as cost inputs to logistics models
- 344 Remy L. de Jong, Rashid I. Al Layla, Willem J. Selen
Alternative water management scenarios for Saudi Arabia
- 345 W.J. Selen and R.M. Heuts
Capacitated Single Stage Production Planning with Storage Constraints and Sequence-Dependent Setup Times
- 346 Peter Kort
The Flexible Accelerator Mechanism in a Financial Adjustment Cost Model
- 347 W.J. Reijnders en W.F. Verstappen
De toenemende importantie van het verticale marketing systeem
- 348 P.C. van Batenburg en J. Kriens
E.O.Q.L. - A revised and improved version of A.O.Q.L.
- 349 Drs. W.P.C. van den Nieuwenhof
Multinationalisatie en coördinatie
De internationale strategie van Nederlandse ondernemingen nader beschouwd
- 350 K.A. Bubshait, W.J. Selen
Estimation of the relationship between project attributes and the implementation of engineering management tools
- 351 M.P. Tummers, I. Woittiez
A simultaneous wage and labour supply model with hours restrictions
- 352 Marco Versteijne
Measuring the effectiveness of advertising in a positioning context with multi dimensional scaling techniques
- 353 Dr. F. Boekema, Drs. L. Oerlemans
Innovatie en stedelijke economische ontwikkeling
- 354 J.M. Schumacher
Discrete events: perspectives from system theory
- 355 F.C. Bussemaker, W.H. Haemers, R. Mathon and H.A. Wilbrink
A (49,16,3,6) strongly regular graph does not exist
- 356 Drs. J.C. Caanen
Tien jaar inflatieneutrale belastingheffing door middel van vermogensaftrek en voorraadaftrek: een kwantitatieve benadering

- 357 R.M. Heuts, M. Bronckers
A modified coordinated reorder procedure under aggregate investment
and service constraints using optimal policy surfaces
- 358 B.B. van der Genugten
Linear time-invariant filters of infinite order for non-stationary
processes
- 359 J.C. Engwerda
LQ-problem: the discrete-time time-varying case
- 360 Shan-Hwei Nienhuys-Cheng
Constraints in binary semantical networks
- 361 A.B.T.M. van Schaik
Interregional Propagation of Inflationary Shocks
- 362 F.C. Drost
How to define UMVU
- 363 Rommert J. Casimir
Infogame users manual
Rev 1.2 December 1988
- 364 M.H.C. Paardekooper
A quadratically convergent parallel Jacobi-process for diagonal
dominant matrices with nondistinct eigenvalues
- 365 Robert P. Gilles, Pieter H.M. Ruys
Characterization of Economic Agents in Arbitrary Communication
Structures
- 366 Harry H. Tigelaar
Informative sampling in a multivariate linear system disturbed by
moving average noise
- 367 Jörg Glombowski
Cyclical interactions of politics and economics in an abstract
capitalist economy

IN 1989 REEDS VERSCHENEN

- 368 Ed Nijssen, Will Reijnders
"Macht als strategisch en tactisch marketinginstrument binnen de distributieketen"
- 369 Raymond Gradus
Optimal dynamic taxation with respect to firms
- 370 Theo Nijman
The optimal choice of controls and pre-experimental observations
- 371 Robert P. Gilles, Pieter H.M. Ruys
Relational constraints in coalition formation
- 372 F.A. van der Duyn Schouten, S.G. Vanneste
Analysis and computation of (n,N) -strategies for maintenance of a two-component system
- 373 Drs. R. Hamers, Drs. P. Verstappen
Het company ranking model: a means for evaluating the competition
- 374 Rommert J. Casimir
Infogame Final Report
- 375 Christian B. Mulder
Efficient and inefficient institutional arrangements between governments and trade unions; an explanation of high unemployment, corporatism and union bashing
- 376 Marno Verbeek
On the estimation of a fixed effects model with selective non-response
- 377 J. Engwerda
Admissible target paths in economic models
- 378 Jack P.C. Kleijnen and Nabil Adams
Pseudorandom number generation on supercomputers
- 379 J.P.C. Blanc
The power-series algorithm applied to the shortest-queue model
- 380 Prof. Dr. Robert Bannink
Management's information needs and the definition of costs, with special regard to the cost of interest
- 381 Bert Bettonvil
Sequential bifurcation: the design of a factor screening method
- 382 Bert Bettonvil
Sequential bifurcation for observations with random errors

- 383 Harold Houba and Hans Kremers
Correction of the material balance equation in dynamic input-output models
- 384 T.M. Doup, A.H. van den Elzen, A.J.J. Talman
Homotopy interpretation of price adjustment processes
- 385 Drs. R.T. Frambach, Prof. Dr. W.H.J. de Freytas
Technologische ontwikkeling en marketing. Een oriënterende beschouwing
- 386 A.L.P.M. Hendriks, R.M.J. Heuts, L.G. Hoving
Comparison of automatic monitoring systems in automatic forecasting
- 387 Drs. J.G.L.M. Willems
Enkele opmerkingen over het inversificerend gedrag van multinationale ondernemingen
- 388 Jack P.C. Kleijnen and Ben Annink
Pseudorandom number generators revisited
- 389 Dr. G.W.J. Hendrikse
Speltheorie en strategisch management
- 390 Dr. A.W.A. Boot en Dr. M.F.C.M. Wijn
Liquiditeit, insolventie en vermogensstructuur
- 391 Antoon van den Elzen, Gerard van der Laan
Price adjustment in a two-country model
- 392 Martin F.C.M. Wijn, Emanuel J. Bijnen
Prediction of failure in industry
An analysis of income statements
- 393 Dr. S.C.W. Eijffinger and Drs. A.P.D. Gruijters
On the short term objectives of daily intervention by the Deutsche Bundesbank and the Federal Reserve System in the U.S. Dollar - Deutsche Mark exchange market
- 394 Dr. S.C.W. Eijffinger and Drs. A.P.D. Gruijters
On the effectiveness of daily interventions by the Deutsche Bundesbank and the Federal Reserve System in the U.S. Dollar - Deutsche Mark exchange market
- 395 A.E.M. Meijer and J.W.A. Vingerhoets
Structural adjustment and diversification in mineral exporting developing countries
- 396 R. Gradus
About Tobin's marginal and average q
A Note
- 397 Jacob C. Engwerda
On the existence of a positive definite solution of the matrix equation $X + A^T X^{-1} A = I$

- 398 Paul C. van Batenburg and J. Kriens
Bayesian discovery sampling: a simple model of Bayesian inference in auditing
- 399 Hans Kremers and Dolf Talman
Solving the nonlinear complementarity problem
- 400 Raymond Gradus
Optimal dynamic taxation, savings and investment
- 401 W.H. Haemers
Regular two-graphs and extensions of partial geometries
- 402 Jack P.C. Kleijnen, Ben Annink
Supercomputers, Monte Carlo simulation and regression analysis
- 403 Ruud T. Frambach, Ed J. Nijssen, William H.J. Freytas
Technologie, Strategisch management en marketing
- 404 Theo Nijman
A natural approach to optimal forecasting in case of preliminary observations
- 405 Harry Barkema
An empirical test of Holmström's principal-agent model that tax and signally hypotheses explicitly into account
- 406 Drs. W.J. van Braband
De begrotingsvoorbereiding bij het Rijk
- 407 Marco Wilke
Societal bargaining and stability
